User Testing Protocol

Prompt: “You want to find a school to volunteer with matching interests. Walk me through how you’d complete that.”

(Hidden from testers but this is the **expected workflow** and results)

1. Look through the Find School options

- a. Clicking into “Find Schools” should navigate to the page successfully
- b. Find School should render all 10 cards of different school
- c. Each card has an image, school name, school location, school’s values, and school’s preferred level of education

2. Finish interest form (Feature 1)

- a. Finding buttons for “Volunteer Now” should lead to form
- b. Users can choose from dropdown menus and submit form

3. View matched results

- a. Should show how many matches are there e.g., (4/4)
- b. “Yes” and “No” button below rendered cards of matches for users to click
- c. Rendered cards should have same number as matched results
- d. Each card contains same format as Find School cards

4. Select matches between “Yes” and “No” (Feature 2)

- a. After choosing, all “Yes” cards will be rendered
- b. Clicking into those cards should show highlighted text of contact information to the schools

5. Log in to save results (Feature 3)

- a. Users can choose to sign in to save results
- b. After signing in, the saved schools should render in “Review your matches” page

We will measure:

- task completion (yes/no)
- user confidence
- satisfaction with matches
- perceived clarity and inclusivity of the form

Follow-up Questions:

1. Are there any places of confusion you would like to note?
2. Are there any other thoughts, suggestions, opinions you would like to express?

Potential Bugs:

- Sometimes clicking too fast into the “Find Schools” page (or scrolling too fast) can make some school cards hard to render. *Workaround*: Refresh page or waiting for a little is usually the best solution for the cards to pop up (usually takes 1-2 seconds to load).
-

Will you create an interactive prototype before you begin coding (e.g. using Figma), or will you work from static wireframes?

- We intend to create static wireframes with color schemes for key pages to visualize the main layout and possible key features/components.

What are the acceptance tests that your team will perform before beginning user testing? Describe the acceptance testing process for at least two key features, including which results would indicate a successful test and which results would indicate a failed test.

- Interest form captures user’s interest correctly to help to identify and clarify their goals and support confidence
- Acceptance:
 - Success:
 - Users (volunteers/schools) find the form inclusive and comprehensive that encapsulates all (or most) of their goals and delivers their personalities
 - Users are able to complete the form and receive matchmaking results that gives them satisfaction (matching goals/attributions)
 - Users are able to feel confidence after filling the form (indication of strong support of their goals and web support for credible matches)
 - Submission rate of forms are acceptable (~50-60% completion rate as baseline according to Google)
 - Failed:
 - Users felt confused and unmotivated by the interest form

- Users felt the form didn't capture their goals and personalities fully, but there's no other way to express it
 - Users felt discouraged after filling the form (e.g., feeling of being disqualified, or wouldn't receive good matches)
 - Low submission/completion rate of forms
- Successfully connect volunteers and schools to support their educational goals
 - Acceptance:
 - Users are able to find a matched school/volunteer to their satisfaction/interest
 - Matched users are able to contact with each other (the contact info provided are helpful)
 - Users are able to shuffle and find more options and interest of schools/volunteers to contact and continue supporting their educational goals
 - Users generally have one or two 'like' swipes from their matches
 - Failed:
 - Users couldn't find matches that interest them
 - Users felt the matches are not related to their goals and interests
 - User couldn't contact with each other after match (e.g., ghosting)
 - Users felt restricted with the options they got matched to
 - Users have no matches swiped to indicate they 'like' the match

What are the limitations of your acceptance tests? List some of the ways that your team's in-house testing environment may differ from the context in which your expected users will be interacting with the product.

- Limitations would be our assumptions of user actions and backgrounds
 - We developed the app so we have clear expectations of how to use it (user flow). Others, not so much.
 - Users may have different interpretations of icons, pictures, or even the questions on the interest form, leading to hindrance in interacting with the product.
 - We have expectations and assumptions of the goals and desired attributes of users — this may lead to product not withholding to broader contexts
 - We may recruit people with similar backgrounds (e.g., friends from INFO) to do user testing, which they may behave similarly to how we designed the web = cannot predict or incorporate user actions and goals outside of the spectrum and make effective edits

How will you conduct user testing?

We will conduct moderated user testing with participants representing both target groups: volunteers and school/organization coordinators.

Process:

1. Recruit participants through campus networks, education organizations, and community contacts.
2. Provide a short scenario (e.g., “You are a volunteer looking to support math tutoring” or “You are a school seeking STEM volunteers”).
3. Ask participants to complete key tasks:
 - Create an account
 - Fill out the interest form
 - Browse/match with a school or volunteer
 - Attempt to contact a match
4. Observe behavior, task completion, and confusion points.
5. Collect feedback via a post-test survey and short interview.

We will measure:

- task completion rate
- time on task
- user confidence
- satisfaction with matches
- perceived clarity and inclusivity of the form

How will you decide which bugs to fix first?

To decide what bugs to fix first, we will prioritize how serious they are and how much they affect users.

- High priority: Bugs that stop important features from working, like submitting the interest form, getting matches, or contacting a match.
- Medium priority: Bugs that make the experience confusing or frustrating, like wrong match results or navigation problems
- Low priority: Minor visual or styling issues

We will keep a list of all bugs, label them by priority, and fix the most important ones first.

How will you re-test the solution after the bug fixes have been completed?

After we believe that the bugs have been fixed, we will then test the bugs by

1. Initially testing through the same journey that led us to discovering the bug
2. Going through different journeys and seeing if the bug still persists there
3. Switch platform and repeat

Our success criteria will be met if the bug isn't there anymore, even through different journeys, including on the alternate platform, no new bugs are present through the fixing of the bug, and users are able to complete tasks smoothly.

Our standards for success of fixing a bug will not be met if the bug still persists using the original or different journeys, even on a different platform, and if the "fix" causes new errors. Additionally, our users should not be confused while completing their tasks therefore, if the fix does cause confusion during this, we will not see this as a success.
